Emerald Stimulants compared to Colombian Emeralds

Emerald simulants are materials that resemble emeralds but differ in chemical, physical, and optical properties. They can be made from substances like green glass, plastic, or other gemstones such as peridot or green garnet. Colombian emeralds, on the other hand, are natural gemstones known for their vibrant green hue, which comes from trace amounts of chromium. They are highly prized for their rarity and quality.

While emerald simulants are more affordable and visually similar to real emeralds, they lack the unique inclusions and depth of color that genuine

Colombian emeralds possess. Colombian emeralds are often considered the finest in the world, making them significantly more expensive.
